NEW JERSEY MENISCAL BEARING KNEE REPLACEMENT

TECHNICAL FIELD

This invention relates to prosthetic joints generally, and more particularly to a prosthesis for replacement of a dysfunctional knee joint.

BACKGROUND ART

Referring now to prior art knee endoprostheses, and in particular to the prior art knee prostheses with patello-femoral replacement, it has been observed that such prior art prostheses have poorly designed patello-femoral interfaces in that they do not provide reasonable congruent patello-femoral contact or sliding engagement over any appreciable range of knee motion.

More particularly, such prior art prostheses typically produce contact stresses which result in yielding and fatigue of the plastic bearing surface, typically present in such prostheses. This result is caused by the fact that the bearing surface of the femoral component, over which the patella prosthesis must pass, generally has several regions or segments of differing shape.

For example, there is typically a fairly long, singly curved segment blending into a first doubly curved segment blending again into a second, and different, doubly curved segment. These varying segments or regions provide the femoral portion of the femoral-tibial articulation, and those segments or regions do not have a common generating curve. Thus, when the patella prosthesis goes through its excursion over the femoral articular flange, the patella prosthesis undergoes a variety of contact conditions, namely, substantial portions of line contact, portions of point contact, and perhaps limited portions of area or congruent area contact. As is known, line contact and point contact conditions generally produce high contact stresses which produce yielding and substantial wear of plastic prostheses. Hence, the extended wear life needed for successful

1 prosthetic implantation is not realized.

2 Referring next to typical prior art tibio-femoral
3 knee prostheses, it has been observed that those prior
4 art knee prostheses which allow axial rotation and
5 anterior-posterior motion in addition to flexion-
6 extension motion have incongruent contact (usually
7 theoretical point-contact) between the femoral and tibial
8 bearing surfaces, producing excessive contact stresses
9 leading to deformation and/or early wear and undesir-
10 ably short prosthetic life. Also, wear products have been
11 shown to produce undesirable tissue reactions which may
12 contribute to loosening of the prosthetic components.

13 Those prior art knee prostheses which do provide
14 congruent or area bearing contact fail to provide the
15 needed axial rotation, or when cruciates are present the
16 needed anterior-posterior motion. This lack of axial
17 rotation and anterior-posterior motion has been shown
18 clinically and experimentally to result in deformation
19 and loosening of the tibial components, and such prosthe-
20 ses now appear to be falling into disuse.

21 Current prostheses of the dislocatable cruciate
22 retaining type, such as the Geomedic knee replacement
23 shown in U.S. Patent No. 3,728,742 issued April 24, 1973
24 to Averill et al., that produce area contact provide
25 only one axis of rotation relative to the femur for the
26 flexion-extension motion. Normal flexion-extension
27 is, however, characterized by a polycentric flexion-
28 extension motion where rotation relative to the femur
29 occurs about many axes. This polycentric motion, which
30 results from the action of the cruciate ligaments and
31 condylar shape, allows for more efficient utilization of
32 muscle forces by providing a posterior shift of the axis
33 when effective quadriceps action is important and an
34 anterior shift when hamstrings effectiveness is important.
35 Furthermore, in the human knee it is this polycentric
36 action, and the shape of the posterior condyles, which

1 influence this motion so as to allow full flexion cap-
2 ability for the knee. Failure to provide appropriate
3 knee geometry inhibits, when cruciate ligaments are present, this
4 natural polycentric motion and thus tends to restrict muscle effectiveness
5 and inhibit flexion. These restrictions tend to increase
6 both loading on the prosthesis (which increases wear
7 or likelihood of deformation or breakage) and loading
8 between prosthesis and bone (which increases the possib-
9 ility of component loosening).

10 Other knee designs, such as the Townley type,
11 avoid overconstraint by introducing incongruency of the
12 articulating surfaces. The incongruency, while necessary
13 to avoid overconstraint, unfortunately results in in-
14 stability and excessive contact stresses.

15 It is further believed that loosening problems
16 result from the direct attachment of plastic prosthetic
17 components to bone through the use of relatively brittle
18 cement that is weak in tension. Specifically, it has
19 been demonstrated that even relatively thick plastic
20 components when loaded in a normal fashion produce
21 undesirable tensile stresses in the acrylic cement
22 commonly used to secure such plastic components to bone.
23 Such loading tends to produce bending of the ~~the~~ plastic
24 component which causes the ends of the plastic
25 component to lift away from the bone, thereby subjecting
26 the bone-cement attachment to tension. As is known,
27 cement has very poor tensile fatigue properties. The
28 bone to which the plastic prosthesis is cemented also
29 appears to be adversely affected by tensile loads.
30 Accordingly, it is believed that these combined effects
31 contribute substantially to prosthetic loosening problems
32 and, specifically, it has been noted where clinical failure
33 due to loosening occurs in a knee prosthesis that it is almost
34 always the plastic prosthesis component which loosens.

35 Another prior art prosthesis problem exists with
36 regard to knee endoprostheses for implantation in those

1 cases wherein the cruciate ligaments are functionally
2 absent but where the collateral ligaments are functional
3 or at least reconstructable. In the absence of cruciate
4 ligaments, the prosthetic replacement must provide
5 anterior-posterior knee joint stability so as to replace
6 that stability otherwise provided by the cruciates.
7 Until recently most such cases were treated by a stable
8 hinge-type knee prosthesis which, unfortunately, appears
9 to suffer from the loosening problems described above
10 and furthermore typically produces substantial bone loss
11 as a result of the relatively great bone resection
12 required for implantation. Necrosis of the bone,
13 caused by altered mechanical bone stresses, is also a
14 problem with the hinge-type knee prostheses. More recent
15 attempts have been made to treat such cases with surface
16 replacement prostheses such as the prostheses known as
17 the Total Condylar and similar knee prostheses. However,
18 these knee prostheses have theoretical point-contact
19 bearing surfaces with their above-noted attendant
20 problems and, in addition, such prostheses tend to have
21 instability and dislocation problems which result, at
22 least in part, from these point-contact bearing surfaces.
23

24 Where the cruciate ligaments are present, most
25 surgeons would prefer their retention, since they
26 provide important internal stabilizers and, together with
27 the condylar geometry of the femur and tibia, control the
28 rotation axis of the knee. Furthermore, these ligaments
29 provide anterior-posterior (A-P) stability. Thus, it is
30 desirable to preserve the cruciate ligaments, even though
31 reasonable stability can be provided by a properly
32 designed full platform type prosthesis.

33 In addition, the action of the cruciate ligaments
34 produces a shift in the rotation axis of the knee which
35 may result in more efficient muscle utilization. Thus,
36 preservation of these structures may provide better
physiological function after knee replacement.

1 Still, it is not clear that the physiological
2 advantages gained in retaining the cruciates outweigh
3 the disadvantages of the design compromises, such as
4 increased bearing surface incongruency and reduced tibial
5 prosthesis bearing area, required to retain these ligaments.
6 Thus, the desirability of retaining the cruciate ligaments
7 in the cases of unicompartmental and tricompartmental
8 replacement is not well established. The design describ-
9 ed herein, however, eliminates or compensates for these
10 design compromises, thus allowing the benefits of
11 cruciate retention with minimal or no apparent loss in
12 the ability of the prosthesis to withstand the loads to
13 which it is subjected.

14 In unicompartmental replacement, the cruciates must
15 be retained in any event since there is insufficient
16 stability in their absence with a unicondylar replacement.
17 Thus, for such cases a design which accommodates the
18 cruciate ligaments is necessary.

19 Unicompartmental replacement with a proper bearing
20 design allows surgical restoration of a single diseased
21 compartment, rather than the sacrifice of normal struc-
22 tures to replace all three compartments of the knee.
23 Further, reducing the number of compartments replaced
24 has the effect of reducing prosthesis wear products.
25 Recent evidence strongly suggests that these wear
26 products produce adverse physiological response to the
27 prosthesis, including an increased tendency for the
28 prosthesis to loosen from its boney attachment.

29 A recent experimental knee concept, the Oxford knee,
30 appears to provide a partial solution to the problem of
31 overconstraint while maintaining congruency by the use
32 of meniscal floating elements. Unfortunately, this knee
33 suffers from several design problems which appear to limit
34 its usefulness. The present invention, the New Jersey
35 Meniscal Bearing Knee Replacement (NJMBK) utilizes similar
36 concepts in an improved fashion in order to avoid some of

1 the anticipated difficulties of the Oxford design.

2 The Oxford knee is shown in FIGURES 1A and 1B. The
3 femoral components 101 consist of two metal spherical
4 segments, each of constant radius. Bearing inserts 102
5 are circular in shape with a shallow spherical superior
6 surface and a flat inferior surface. The tibial onlays
7 103 consist essentially of two flat plates with fixation
8 by means of a fin 104 at the medial edge of each such
9 flat plate.

10 There are several serious problems with the design
11 of the Oxford knee of FIGURES 1A and 1B. The most basic
12 problem is the potential for dislocation of bearing
13 inserts 102 resulting from the limited flexion range of
14 the device. As can be seen from FIGURES 2A and 2B, the design

20 15 provides excellent congruent contact up to about 90°
16 flexion. Beyond that point a surface of constant
17 radius cannot provide proper contact within the geometric
18 constraints imposed by having to fit the prosthesis to
20 19 the human knee. Flexion substantially beyond 90°
20 produces edge contact and resulting deformation and
20 21 possible dislocation of bearing inserts 102. Although 90°
22 of flexion is satisfactory from a functional standpoint,
23 it is impractical to limit motion to this range, since
24 activities will be encountered (such as sitting onto a
25 low chair, or returning to the standing position after
26 sitting in a low chair) where flexion substantially
27 exceeds 90°.

28 The problem of insert dislocation is made more
29 severe by axial rotation of the knee, as is shown in
30 FIGURES 3A and 3B. In FIGURE 3A, there is shown the
20 31 position of bearing inserts 102 at 90° flexion, but with
32 no axial rotation of the knee. In FIGURE 3B there is
20 33 shown the position of bearing inserts 102 at 90° flexion,
34 but with 15° (solid lines) and 30° (dashed lines) of
35 axial rotation as well. There is a pronounced overhang
36 of bearing inserts 102, with resultant risk of dislocation,

20

1 under the combination of 90° flexion and 30° axial
2 rotation of the knee. A B

3 Normal distraction of one compartment of the knee
4 during the swing phase of walking, as depicted in
5 FIGURE 4, also leaves bearing insert 102 of the prior-art
6 Oxford knee free to dislocate.

7 A further disadvantage of the Oxford knee arises
8 from the shallowness and placement of the arcs of the
9 contact surfaces, as can be seen from FIGURES 5A and
10 5B. In FIGURE 5A there is shown a normal knee joint,
11 with the anatomical ramp height designated 105. Note,
12 in FIGURE 5B, that the Oxford prosthesis ramp height 106
13 is substantially less than the anatomical ramp height 105,
14 and therefore the Oxford prosthesis provides less than
15 normal medial-lateral stability. Thus, when medial
16 lateral shear loads are encountered, additional stress
17 is placed on the cruciate ligaments, which may be already
18 compromised by bone resection. Furthermore, such loading,
19 in conjunction with flexion or extension, will produce
20 undesirable rubbing between the edges 107 of bearing
21 inserts 102 and the cut edges 108 of the tibial bone.

22 Other weaknesses of the Oxford design include lack
23 of accommodation for patella replacement, and tibial
24 plateau components with relatively poor load-bearing
25 properties, as will be described later.

26 An alternate embodiment of the Oxford knee which
27 attempts to deal with the problem of dislocation is
28 depicted in FIGURES 6A-D. Unfortunately, this design has
29 several deficiencies which make it unworkable, at least
30 with materials now commonly used for such components.
31 The anterior-posterior (A-P) travel limit is greatly
32 restricted compared to that of the present invention.
33 There is substantial unsupported area 109 of plastic
34 bearing insert 102, as can be seen from the cross
35 sectional view of FIGURE 6C. Flexure of the plastic
36 bearing insert 102 will occur, transferring load to the

8

1 remaining areas and thus greatly increasing bearing
2 compressive stresses. High stress will occur in the inner
3 cavity at the head of retaining pin 110, particularly at
4 the edge of retaining pin 110 and at the contact between
5 the end of retaining pin 110 and the inner cavity, as
6 can be seen from the cross-sectional view of FIGURE 6D.
7 Furthermore, the use of retaining pin 110 makes install-
8 ation of the bearing element difficult after implantation
9 of femoral and tibial components, since it is necessary
10 to separate the knee joint by stretching the ligaments
11 an amount equal to the pin height in addition to the
12 separation normally required to install bearing inserts
13 102.

Cl

SUMMARY OF THE INVENTION

2 The present invention is directed to an improved
3 prosthesis for the replacement of all or a portion of
4 a dysfunctional human knee joint.

5 An object of the present invention is to provide a
6 knee prosthesis in which shift of the bearing insert with
7 knee flexion is similar to the normal anatomical shift in
8 the center of the area of contact between femoral and
9 tibial condyles.

10 A further object of the present invention is to
11 provide a knee prosthesis which facilitates rotation
12 about one or more axes, even in the presence of perfect
13 congruency and rigidity of the bearing surfaces.

14 A further object of the present invention is to
15 provide a knee prosthesis with greater dislocation
16 height, and hence improved dislocation characteristics,
17 than are available with prior-art floating bearing insert
18 type knee prostheses.

19 A further object of the present invention is to
20 provide a knee prosthesis with improved medial-lateral
21 stability, substantially unaffected by axial rotation or
22 anterior-posterior (A-P) shift of the bearing insert or
23 inserts.

24 A further object of the present invention is to
25 provide a knee prosthesis which substantially reduces the
26 possibility of tipping or dislocation of the bearing
27 insert or inserts.

28 A further object of the present invention is to
29 provide a knee prosthesis which allows full flexion of
30 the reconstructed knee.

31 A further object of the present invention is to
32 provide a knee prosthesis allowing retention of the
33 cruciate ligaments and capable of both effective patello~~femoral~~
34 femoral and tibio-femoral articulation.

35 A further object of the present invention is to
36 provide a knee prosthesis having reduced tendency toward

1 loosening and collapse, as compared with prior-art
2 floating bearing insert type knee prostheses.

3 A further object of the present invention is to
4 provide a knee prosthesis allowing retention of the cruci-
5 ate ligaments in which contact stresses between the tibial
6 platform and the tibia are minimized.

7 A further object of the present invention is to
8 provide a knee prosthesis design which is adaptable to
9 embodiments for unicompartmental, bicompartamental, and
10 tricompartmental knee replacements.

DR A

1 BRIEF DESCRIPTION OF THE DRAWINGS

2 *P* A complete understanding of the invention may be
3 obtained from the detailed description which follows,
4 together with the accompanying drawings, wherein:

5 *P* FIGURES 1A and 1B are diagrammatic views of the
6 prior-art Oxford knee.

7 *20* FIGURES 2A and 2B illustrate the prior-art Oxford
8 knee at 85° and 120° (respectively) flexion, showing the
9 excess posterior displacement of the bearing inserts at
10 *W* 85° flexion. Two possible dislocation modes of the bearing
11 inserts are shown at 120° flexion.

12 *20* FIGURES 3A and 3B also depict the prior-art Oxford
13 knee. FIGURE 3A shows, in plan view, the position of
14 the bearing inserts at 90° flexion with no rotation of
15 the knee. FIGURE 3B shows the positions of the bearing
16 inserts at 90° flexion in the presence of axial rotations
17 of 15° and 30°.

18 *P* FIGURE 4 illustrates the possibility of dislocation
19 of the bearing inserts, in the prior-art Oxford knee,
20 in the swing phase of walking.

21 FIGURES 5A and 5B compare the anatomical ramp height
22 with the ramp height provided by the prior-art Oxford
23 knee prosthesis.

24 FIGURES 6A through 6D illustrate some of the dis-
25 advantages which result from a design modification to
26 partially constrain the bearing inserts of the prior-art
27 Oxford knee.

28 FIGURES 7 through 9 show the femoral component
29 of the present invention, the New Jersey Meniscal Insert
30 Knee.

31 FIGURES 10 through 12 show the intermediate patella
32 bearing component according to the present invention.

33 FIGURES 13 and 14 show the patella fixturing compo-
34 nent according to the present invention.

35 FIGURES 15 through 17 show the tibial platform
36 component according to the present invention.

12

1 FIGURES 18 through 21 show the intermediate tibial
2 bearing component according to the present invention.

3 FIGURE 22 illustrates the manner in which the surface
4 of the femoral component according to the present invent-
5 ion is generated by a series of segments of surfaces
6 of revolution.

7 FIGURE 23 illustrates the manner in which the several
8 bearing surfaces of the present invention are generated
9 by rotating a common generating curve about a particular
10 generating axis at pairs of major generating radii.

11 FIGURE 24 shows the orientation of the patella
12 prosthesis relative to the femoral component at full
13 extension of the knee.

14 FIGURE 25 illustrates the role of the fixturing fins
15 (of the patella fixturing component) in resisting tipping
16 loads.

17 FIGURE 26 shows the button portion of the patella
18 fixturing component, which is used to retain the intermed-
19 iate patella bearing component.

20 FIGURE 27 shows the manner in which the present
21 invention permits rotation of the patella with respect
22 to the femoral bearing surface.

23 FIGURES 28A and 28B illustrate the relatively low patello-
24 femoral compression force present at full extension of
25 the knee.

26 FIGURES 29A and 29B illustrate the somewhat greater patello-
27 femoral compression force present in the load-bearing
28 stance phase of the normal walking cycle.

29 FIGURES 30A and 30B illustrate the much greater patello-
30 femoral compression force present in deep knee flexion.

31 FIGURE 31 is an inferior view of the distal femur,
32 showing the femoral anterior articular cartilage involved
33 in patello-femoral articulation, as well as the femoral
34 posterior articular cartilage involved in tibio-femoral
35 articulation.

36 FIGURES 32A and 32B show the manner in which the

1 intermediate tibial bearing components are held in a
2 forward position, on the tibial platform, by virtue of
3 the shape of the bearing surface of the femoral component.

4 FIGURES 33A and 33B show the manner in which the
5 intermediate tibial bearing components move posteriorly
20 6 with flexion of the knee. FIGURE 33A shows 15° flexion,
7 while FIGURE 33B shows 120° flexion.

8 FIGURE 34 is a cross-sectional view of the curved
9 track of the tibial platform component according to the
10 present invention.

11 FIGURES 35A and 35B illustrate the manner in which the
12 intermediate tibial bearing components move slightly
13 closer together as they move forward and rearward from
14 a central position in the curved track of the tibial
15 platform component.

16 FIGURE 36 illustrates the manner in which the inter-
17 mediate tibial bearing components move slightly closer
18 together as the femur moves posteriorly.

19 FIGURES 37A and 37B show the manner in which the use of an
20 eccentric bearing insert (i.e. the intermediate tibial
21 bearing component) allows a relatively great inward
22 shift of the bearing insert with little incongruency.

23 FIGURES 38A through 38C illustrate several advan-
24 tages of the intermediate tibial bearing component
25 according to the present invention. The larger ~~planform~~
26 (relative to that of the circular bearing insert of the
27 prior-art Oxford knee) is shown in FIGURE 38A. FIGURE 38B
28 illustrates the greater dislocation height of the present
29 invention, and FIGURE 38C illustrates the non-central
30 spherical radius of the present invention.

31 FIGURES 39A and 39B illustrate the undesirable tensile
32 stresses produced in the prosthesis-bone interface by
33 the MacIntosh type tibial onlays of the prior-art
34 Oxford knee.

35 FIGURES 40A and 40B show the tibial platform of a unicompartmental
36 version of the present invention.

14

1 FIGURES 41A and 41B show the manner in which the
2 spike of the tibial platform of the unicompartmental version
3 of the present invention resists both tipping and compressive
4 loads.

5 FIGURES 42A and 42B compare the tibial platform com-
6 ponent of the present invention with a prior-art prosthesis
7 utilizing a flexible platform, which is ineffective in pro-
8 ducing any load-sharing across the prosthesis-bone interface.

9 FIGURES 43 and 44 show the femoral component of a
10 unicompartmental version of the present invention.

11 FIGURES 45 and 46 show an implanted bicompartmental
12 version of the present invention, utilizing a pair of
13 individual femoral components.

14 FIGURES 47A and 47B show an implanted unicompartmental
15 version of the present invention.

16 FIGURES 48, 49 and 50 illustrate an ankle prosthesis
17 according to the present invention. FIGURE 48 is a cross-
18 sectional view of the prosthesis, as indicated in FIGURE 50.

19 FIGURES 51 and 52 show the implanted ankle prosthesis
20 according to the present invention.

21 FIGURES 53 and 54 show an anatomical ankle, for
22 comparison with the implanted ankle prosthesis of
23 FIGURES 51 and 52.

24 FIGURE 55 shows, in schematic cross-section, an
25 alternative track (consisting of just a shoulder, rather
26 than a channel) suitable for applications where force
27 loads applied to the prosthetic joint are such as to
28 insure retention of the bearing insert against the shoulder.

DEA

1 DETAILED DESCRIPTION OF THE INVENTION

2 *P* Referring now to FIGURES 7-21, there is shown an
3 endoprosthesis embodying the present invention which has
4 been referred to as a tricompartmental knee prosthesis
5 and which includes the femoral component 111 best shown
6 in FIGURES 7, 8, and 9; the patella prosthesis 112 shown in
7 FIGURE 27 and comprising the intermediate patella bearing component 113
8 best shown in FIGURES 10, 11, and 12, and the patella
9 fixturing component 114 shown in FIGURES 13 and 14;
10 and the tibial prosthesis 115 shown in FIGURE 27 and comprising
11 the tibial platform component 116 best shown in FIGURES 15, 16, and
12 17 and the intermediate tibial bearing components 117
13 shown in FIGURES 18, 19, 20, and 21.

14 Referring now to FIGURES 7, 8, and 9, there is
15 shown in detail the femoral component 111 which includes,
16 in the counter-clockwise anterior ~~or~~ *N* posterior direction,
17 a flange 118 formed integrally with two condyles 119-119.
18 The femoral component 111 also includes a pair of *M*
19 fixturing posts; only one fixturing post, post 120,
20 being shown. The outside surface of the flange 118
21 provides most of the bearing surface for patella artic-
22 ulation. The condyles 119 are provided for replacing the
23 condylar surfaces of the human femur. The bearing surfaces
24 of flange 118 and condyles 119-119 are referred to gener-
25 ally as the bearing surface 121. In accordance with the
26 teaching of the present invention, bearing surface 121
27 in the counterclockwise anterior to posterior direction
28 is a smooth, continuous surface formed by a series of
29 segments of surfaces of revolution the respective
30 shapes of which are generated or defined by rotating a
31 common generating curve (generally identified as F)
32 around a plurality of generating axes at respective pairs
33 of major generating radii (or each at a respective major
34 generating radius where the radii of each pair are equal)
35 and through respective angles or rotation.

36 This common generating curve F is a smooth continuous

16

1 plane curve and as may be understood from FIGURE 7 the
2 shape of which is defined by (i) two arcs K1 and K2
3 struck, respectively, by two radii A1 and A2 from re-
4 spective centers H1 and H2 separated by a distance X;
5 (ii) two tangent lines 123 and 124 respectively tangent
6 to the arcs K1 and K2 and at angles α_1 and α_2 ,
7 respectively, with respect to a line G tangent to arcs
8 K1 and K2; and (iii) an arc K3 struck by radius B from
9 center H3 and wherein arc K3 is also tangent to the tangent
10 lines 123 and 124.

11 Referring now to FIGURE 23, where a further under-
12 standing of the general teachings of the present invention
13 is illustrated, it will be understood that the shape
14 of the bearing surface 121 (FIGURE 7) is defined or
15 generated by a series of segments of surfaces of revolut-
16 ion each of which segments is defined or generated by
17 rotating the common generating curve F around a respective
18 generating axis at respective pairs of major generating
19 radii (or each at a major generating radius where the
20 radii of each pair of major generating radii are equal)
21 and through a respective angle of rotation. In generat-
22 ing each segment of a surface of revolution, the common
23 generating curve F is oriented with respect to a generating
24 axis by a pair of major generating radii D1 and D2
25 which are the respective distances (shortest distances)
26 from points M1 and M2 where the common generating
27 curve F contacts tangent line G as shown in FIGURE 23.

28 Referring now to FIGURE 22, it will be understood
29 that this figure is a diagrammatic illustration showing
30 the manner in which the series of segments of surfaces
31 of revolution S1, S2, S3 and S4 defining the shape of the
32 bearing surface 121 are generated and where the curve Q
33 represents the trace of points M1 and M2 as viewed along
34 line G (FIGURE 23) resulting from the rotations about
35 the respective generating axes generating the surface
36 segments. It will be further understood that the shape

1 of the bearing surface 121 is defined by a series of
2 segments of surfaces of revolution where each pair of
3 major generating radii D1 and D2 for generating each
4 segment decrease in length respectively as rotation of
5 the generating curve F proceeds about each generating axis
6 in the counterclockwise anterior to posterior direction
7 as viewed in FIGURE 22. In the present embodiment ~~and as~~
8 ~~illustrated in FIGURE 23~~, the pairs of major generating
9 radii D1 and D2 are equal in each instance and may in
10 each instance be replaced by a single major generating
11 radius R (i.e. R1, R2, R3 and R4) as shown in FIGURE 22.
12 In this embodiment, the bearing surface 121 consists of
13 four segments of surfaces of revolution S1, S2, S3 and S4.

14 S1 is generated by rotating the common generating
15 curve F through an angle θ_1 about generating axis C1
16 perpendicular to the plane of FIGURE 22 at a major
17 generating radius R1. In the present embodiment, R1 is
18 equal to infinity and since only the intermediate patella
19 bearing component 113 of FIGURES 10, 11, and 12 artic-
20ulates with segment S1, it will be referred to as the
21 patello-femoral bearing surface segment.

22 Segment S2 is generated by rotating the common
23 generating curve F through an angle θ_2 about generating
24 axis C2 parallel to C1 at a major generating radius R2
25 where R2 is equal to radius A1 which is equal to A2 in
26 FIGURE 7; since such radii are equal, it will be under-
27 stood that segment S2 has two spherical surfaces.
28 For continuity and smoothness of bearing
29 surface 121, axis C2 must lie on the ray L1 passing through
30 C1 and defining the end of segment S1. This segment (S2)
31 is of special importance since both the intermediate
32 patella bearing component 113 and the intermediate tibial
33 bearing component 117 articulate with this segment and
34 since the greatest loads on these components during
35 normal walking occur when they articulate against this
36 femoral bearing segment. This segment (S2) will, therefore,

1 be referred to as the primary load bearing surface
2 segment.

3 Segment S3 is generated by rotating the common
4 generating curve F through an angle θ_3 about generating
5 axis C3 parallel to C2 located at major generating radius
6 R3 where R3 is less than R2. Again, for continuity and
7 smoothness of bearing surface 121, axis C3 must lie on
8 ray L2 passing through C2 and defining the end of
9 segment S2.

10 Finally, segment S4 is generated by rotating the
11 common generating curve F through an angle θ_4 about
12 generating axis C4 parallel to C2 located at major
13 generating radius R4 which is less than R3. Again for
14 continuity and smoothness of bearing surface 121, axis C4
15 must lie on ray L3 passing through C3 and defining the
16 end of segment S3. These latter two segments will be
17 referred to, respectively, as the first and second
18 posterior femoral bearing surface segments.

19 Referring again to FIGURE 8, it will be understood
20 that FIGURE 8 is a sectional view of an actual embodi-
21 ment of the present invention as shown in FIGURE 7 and
22 that the segments of surfaces of revolution S1, S2, S3
23 and S4 shown in FIGURE 22 are also shown in FIGURE 8
24 at their respective locations.

25 In one embodiment of the present invention, the
26 respective angles θ and each respective major generating
27 radius are as follows:

28	SEGMENT	θ (DEGREES)	MAJOR GENERATING RADIUS (inches)
29	S1	0	∞ (displacement 0.612 inches)
30	S2	107.75	1.388
31	S3	62.25	0.801
32	S4	62	0.578

36 Referring again to FIGURES 8 and 22, it will be noted

1 that the generating axes C1, C2, C3 and C4 are parallel
2 with respect to each other and it will be understood
3 that the tangent line G is oriented substantially
4 parallel to the generating axes. However, in accordance
5 with the teachings of the present invention, such need
6 not be the case and the generating axes may be oriented
7 other than parallel with respect to each other and, as
8 shown in the general case illustrated in FIGURE 23, the
9 tangent line G may be oriented other than parallel to
10 the generating axes.

11 Referring again to the patella prosthesis and in
12 particular to the intermediate patella bearing component
13 113 of FIGURES 10, 11, and 12, it will be understood that
14 in accordance with the further teachings of the present
15 invention such intermediate patella bearing component 113
16 provides a load-bearing surface indicated by general
17 numerical designation 125 for engaging the bearing surface
18 121 of femoral component 111 and which load bearing
19 surface 125 includes a primary load bearing surface
20 segment 126, a pair of secondary load bearing surface
21 segments 127 and 128 and a pair of transition segments
22 129 and 130 between 126 and 127 and 126 and 128 respect-
23 ively. Further, it will be understood in accordance
24 with the teachings of the present invention that the
25 shape of the load bearing surface 125 of the intermediate
26 patella bearing component 113 is defined or generated
27 by the common generating curve F used to generate the
28 segments S1-S4 of the bearing surface 121 of femoral
29 component 111. Referring to FIGURE 11, it will be
30 understood that the common generating curve F is rotated
31 through an angle θ_5 (in one embodiment angle θ_5 equals
32 20°) about generating axis C5 at the pair of major gener-
33 ating radii D1 and D2 shown in FIGURE 23, where D1 and
34 D2 are each equal to major generating radius R2 shown in
35 FIGURE 22, to define the shape of the primary load
36 bearing surface segment 126. Therefore, the patella

74

20

20

1 primary load bearing surface segment 126 congruently
2 matches the primary load bearing surface segment S2 of
3 femoral bearing surface 121 and, upon articulating
4 therewith, engages the primary femoral bearing surface
5 segment S2 in sliding area contact. The secondary load
6 bearing surface segments 127 and 128 of the patella
7 load-bearing surface 125 of FIGURE 11 likewise match
8 the patella femoral bearing surface segment S1 of
9 bearing surface 121 (in FIGURE 8) and hence their
10 shapes are defined or generated by rotating the common
11 generating curve F about an axis C6 at infinity (and
12 parallel to axis C5) as was done in generating the
13 shape of segment S1 of femoral bearing surface 121.
14 Therefore, the patella prosthesis secondary load-bearing
15 surface segments 127 and 128 congruently match the
16 patello-femoral bearing surface segment S1 of femoral
17 bearing surface 121 and, upon articulating therewith,
18 engage the femoral bearing surface segment S1 in sliding
19 area contact. The transition segments 129 and 130
20 are defined by rotating the common generating curve F
21 through an angle θ_6 about axes C7 and C8 respectively at
22 a pair of negative generating radii (directed to opposite
23 sides of common generating curve F from those shown in
24 FIGURE 23), both about 0.30 inch in one embodiment.
25 These transition segments 129 or 130 engage, in line
26 contact, segments S2 and S1 of femoral bearing surface
27 121 near their interface as the contacts shift from
28 segment S2 of the femoral bearing surface 121 with the
29 primary load bearing segment 126 to contact between femoral
30 segment S1 and the secondary load bearing segments 127
31 and 128.
32 In another embodiment of the patella prosthesis of
33 the present invention, secondary load bearing surfaces
34 127 and 128 are inclined downwardly with respect to the
35 horizontal (as viewed in FIGURE 11) to better accommodate
36 the orientation of the patella prosthesis 112 with respect

21

1 to the femoral component 111 during full extension of
2 the human knee as shown in FIGURE 24 and therefore to
3 provide a more uniform load distribution on the secondary
4 load bearing surface segment 127 or 128.

5 The intermediate patella bearing component 113 is
6 retained on the remnant of the human patella by use of
7 the patella fixturing component 114 of FIGURES 13 and 14.
8 Patella fixturing component 114 may be suitably affixed
9 to the remnant human patella, using an acrylic grouting
10 agent or cement, by crossed fixturing fins 131 and 132
11 on the dorsal side of the metal plate 133. Such fixturing
12 fins resist tipping loads, as shown in FIGURE 25, and,
13 in addition, provide a reinforcing effect which allows
14 the use of a thin metal plate 133, which is desirable,
15 since one wishes to minimize the change in overall
16 patella thickness resulting from prosthetic replacement
17 so as not to adversely affect patella function, skin
18 closure after surgery and cosmesis. The fixturing fins
19 131, 132 and metal plate 133 reinforce and strengthen
20 the patella remnant and minimize the possibility of its
21 fracture. The opposite or ventral side of metal plate
22 133, FIGURE 13, which comprises the bulk of the secondary
23 fixturing component bearing surface which mates with the
24 secondary bearing surface 134 on the intermediate
25 patella bearing component 113, is provided with a
26 button 135 which retains intermediate patella bearing
27 component 113 on the patella fixturing component 114 with
28 a snap fit. As shown in FIGURES 13 and 26, the outer
29 diameter of the button 135 is formed from a curve with
30 two tangent radii which produce a smooth retaining male
31 surface 136 when mated with correspondingly shaped female
32 surface 137 (FIGURE 10) provided on the intermediate
33 patella bearing component 113. These shapes allow easy
34 entry of the male into the female component without
35 producing the permanent deformation characteristic of
36 conventional snap-fit configurations. The mating conical

2.2

1 sections provide additional secondary compressive and
2 thrust bearing surfaces. The button 135 is provided with
3 a generally conical shaped bearing surface 138 for
4 rotatably engaging the correspondingly shaped conical
5 secondary bearing surface 134 (FIGURE 10) provided on the
6 intermediate patella bearing element 113 in congruent or
7 area rotational engagement to permit rotation of the
8 patella with respect to femoral bearing surface 121 and
9 the distal end of the femur about axis A8 (FIGURE 27).

10 Further, and referring to FIGURE 13, the patella
11 fixturing component 114 is provided with a pin 139 for
12 engaging a corresponding, curved slot 140 formed in the
13 intermediate patella bearing component 113 (FIGURE 10)
14 to limit the relative rotation between intermediate patella
15 bearing component 113 and the patella fixturing component
16 114 and thereby prevent disorientation between the inter-
17 mediate patella bearing component 113 and the femoral
18 component 111 during implantation and subsequently during
19 actual use. Furthermore, this limited rotation has been
20 found to be reasonably necessary since effusion (build
21 up of blood) post-operatively may temporarily lift the
22 load-bearing surface 125 of the intermediate patella
23 bearing component 113 free of the restraining effects
24 of the femoral component 111.

25 It will be further noted, as shown in FIGURES 10-14,
26 that the intermediate patella bearing component 113 and
27 patella fixturing component 114 are made symmetrical
28 about a plane passing through the center of the primary
29 load bearing surface 126 and through the generating axis
30 C5 producing primary load-bearing surface segment 126,
31 so as to allow the use of the same patella prosthesis in
32 either the right or the left knee. It is for this reason
33 that two secondary load bearing segments (127 and 128)
34 are provided on the load bearing surface 125.

35 Referring now to FIGURES 28A, 28B, 29A, 29B, 30A, and 30B, there
36 is illustrated diagrammatically the manner in which the patello-femoral

1 portion of the tricompartmental prosthesis provides
2 area or congruent sliding contact between the bearing
3 surface 121 of the femoral component 111 and the load
4 bearing surface 125 of the intermediate patella bearing
5 component 113 over the important phases of the range of
6 motion commonly experienced by the human knee, providing
7 line contact between such bearing surfaces only during a
8 brief transitional phase. Referring first to FIGURES 28A and 28B,
9 it will be noted that at full knee extension the quadri-
10 ceps muscle group provides a quadriceps force F_Q which in
11 normal activities is quite low at full extension.
12 Because of the orientation of the force F_Q the resultant
13 patello-femoral compression force R of FIGURE 28B is only
14 a small fraction of force F_Q . During this phase of human
15 knee action there is area contact between the bearing
16 surface segments S1 and 127 (or 128) of the femoral
17 and patella components, respectively. See FIGURES 8
18 and 11.

19 Referring now to FIGURES 29A and 29B wherein the load
20 bearing stance phase experienced during the normal
21 walking cycle is illustrated diagrammatically, it will be
22 noted here the quadriceps force F_Q is greater and the
23 resultant patello-femoral compression force R is much
24 greater than at the full extension illustrated in FIGURES 28A and
25 28B. This result is attributable to the greater quad-
26 riceps force F_Q and the smaller included angle between
27 the quadriceps force F_Q and the patella ligament force
28 $F'Q$. Of course, as is known, even greater flexion angles
29 are experienced by the human knee during stair climbing
30 and descent and hence in these activities even greater
31 patella bearing resultant forces R occur.

32 It will be understood that during the short transition
33 phase in moving from segment S1 to segment S2 that
34 transition segments 129 or 130 of the patella load-
35 bearing surface 125 are in sliding line contact with the
36 femoral bearing surface 121. As is further known, during

24

1 the most common and hence most important human knee
2 activity, namely level walking, there is no substantial
3 quadriceps activity or force present until approximately
4 10° of knee flexion is achieved at which the patella
5 articulation of the prosthesis of the present invention
6 has just entered the primary load bearing surface segment
7 S2 wherein there is sliding area contact between the
8 femoral bearing surface segment S2 and the patella
9 primary load bearing segment 126. Thus, the above-noted
10 transitional and hence momentary line contact is not of
11 serious concern since at this time the quadriceps force
12 F_Q is relatively small and even if it were substantial
13 the resultant compressive force R would still be quite low
14 because of the large included angle between forces F_Q and
15 $F_{Q'}$. Area contact is only needed during the walking load
16 bearing and other activity phases where compression forces
17 R are significant.

18 The regions S1 and S2 on the femoral component 111
19 and corresponding transition segments 129 or 130 and the
20 primary and secondary load bearing surface segments
21 126 and 127 (or 128) are needed to produce anatomical
22 patello-femoral articulation wherein at full extension
23 as the superior aspect of the patella lifts off the
24 femur as in FIGURE 28A and yet allow central area contact
25 engagement at moderate and full flexion as shown in
26 FIGURES 29A and 30A.

27 Referring now to FIGURES 30A and 30B wherein deep knee
28 flexion is illustrated diagrammatically, it will be seen
29 that it is during deep knee flexion that the patello- femoral compressive load R is greatest. It will be
31 understood, and as illustrated in FIGURE 30A, the patella
32 load bearing surface 125 (FIGURE 11) articulates with the
33 same surface segment S2 (FIGURE 8) wherein the tibio- femoral articulation occurs during full extension, thus,
35 the primary load bearing surface segment S2 of bearing
36 surface 121 supplies the femoral bearing surface for both

1 articulations (patello-femoral and tibio-femoral artic-
2 ulations) at times of greatest loading during the walking
3 gait cycle, and this commonality is a significant feature
4 of the present invention. Of course, as is known to
5 those familiar with the anatomy of the human knee, this
6 situation (common articulation between a portion of the
7 human condyles and both the patella and tibial bearing
8 surfaces) is not present in the anatomical human knee.

9 As shown in FIGURE 31, in the human knee the
10 femoral anterior articular cartilage against which the
11 human patella articulates is distinct from that which
12 articulates with the tibia. Such natural structures adapt
13 during development of the human knee to produce precise
14 mating of the structural and articulation elements of
15 the knee but such precision of mating is not practical
16 in replacement knee prostheses because of the large
17 individual variations found in different human knees,
18 as well as the manufacturing and surgical difficulties
19 involved in reproducing such precision. Thus, the use
20 of a common femoral prosthesis primary load bearing sur-
21 face segments S2 for both the patella and tibial artic-
22 ulations represents a significant feature in providing
23 the needed sliding area engagement or congruency of art-
24 iculation for extended wear life.

25 Referring again to FIGURE 10, it will be noted that
26 the depth of engagement of the patella load bearing sur-
27 face 125 into the femoral bearing surface 121, distance
28 T in FIGURE 10, is substantial and hence allows substan-
29 tial subluxation resistance to side thrust loads. It has
30 been found that in individuals where this dimension is
31 small or excessive knee valgus is present, subluxation
32 of the patella is common. Yet in many known prior art
33 devices, the corresponding depth of engagement is in-
34 adequate or non-existent. Further, and referring again
35 to FIGURES 10 and 13, it will be noted that area rotatable
36 mating fit (bearing surfaces 134 and 138) between the

1 intermediate patella bearing component 113 and the
2 patella fixturing component 114 allows a rotation there-
3 between and this rotation is highly desirable to accom-
4 modate possible surgical misalignment during implantation,
5 as well as the small, naturally observed, patella rotation
6 with respect to the human femur during flexion-extension
7 movements.

8 Referring now to FIGURES 18, 19, 20 and 21, and to
9 the intermediate tibial bearing component 117 shown
10 therein, this component provides a primary load bearing
11 surface 141 on its superior side and a second bearing
12 surface 142 on its inferior side. The primary load bear-
13 ing surface 141 is also formed as a surface of revolution
14 and its shape is defined or generated by the common
15 generating curve the same as or very similar to curve F
16 used to generate the shape of segments S1-S4 of femoral
17 bearing surface 121 and the shape of patella bearing
18 surface 125.

19 Referring now to FIGURE 19, it will be understood
20 that the shape of the primary load bearing surface 141
21 is defined by rotating the common generating curve sub-
22 stantially similar to curve F through an angle θ_6 (in
23 one embodiment of the present invention θ_6 equals 60
24 degrees) about generating axis C6 at the same major
25 generating radii D1 and D2 shown in FIGURE 23 where D1 and
26 D2 are again each equal to R2 shown in FIGURE 22.
27 Therefore, the tibial primary load bearing surface 141
28 is in substantial area contact with the primary load
29 bearing surface segment S2 of femoral bearing surface 121
30 and, upon articulating therewith, engages the femoral
31 primary bearing surface segment S2 in sliding area contact.
32 Therefore, substantially congruent articulation is
33 provided at the tibio-femoral joint interface for
34 approximately 36 degrees of knee flexion wherein the
35 greatest loads during the walking cycle are experienced
36 as indicated in FIGURES 29A and 29B.

1 The geometry and particularly the shape of load
2 bearing segment S2 are configured so that, in addition to
3 producing the favorable patello-femoral and tibio~~o~~
4 femoral articulation described, the intermediate tibial
5 bearing components 117 are held in a forward position
6 on the tibial platform 116, as shown in FIGURES 32A and
7 32B. As the knee is flexed slightly the femur, and thus
8 the intermediate tibial bearing components 117, move
9 rearward relative to the tibia so they then occupy a
10 generally central position on the tibial platform 116,
11 as shown in FIGURE 33A. Additional flexure produces a
12 small additional posterior shift of intermediate tibial
13 bearing components 117 as a result of further anterior
14 displacement of the tibia relative to the femur and as
15 a result of femoral condylar geometry, as shown in FIGURE
16 33B. This posterior shift is reduced at flexion angles
17 above 40° by the use of small major generating radii in
18 segments S3 and S4; shown in FIGURE 8, in the New Jersey
19 Meniscal Insert Knee Replacement. The use of smaller
20 major generating radii in segments S3 and S4 allows full
21 flexion without excessive shift of intermediate tibial
22 bearing components 117, an important feature of the present
23 invention that is not to be found in the prior-art Oxford
24 knee.

25 The 0 to 90 degree flexion-extension range includes
26 almost all strenuous activities in which an individual
27 with an endoprosthesis is likely to engage. Articulation
28 in the 35-95 degree range occurs in the first posterior
29 femoral bearing segment S3 of FIGURE 8 and hence there is
30 line contact as indicated in FIGURE 30A. Although such
31 line contact or incongruency is less desirable than
32 sliding area contact, it produces acceptably low contact
33 stresses while allowing sufficient flexion necessary for
34 normal activities since loads during walking in this
35 phase of flexion are much less than in the 0-36 degree
36 range or area contact phase. Heavy joint loading in this

1 range of knee motion occurs much less frequently than in
2 the 0 to 36 degree range and thus higher periodic or
3 transitional stresses can be tolerated without producing
4 fatigue or excessive wear. Flexion from 95 degrees to 140
5 degrees is accommodated by the second posterior femoral
6 bearing segment S4 of the femoral prosthesis (FIGURE 8)
7 and expected stresses at such flexion angles are such that
8 serious permanent deformation is not anticipated except
9 perhaps during deep knee bend exercises such as deep
10 squats, which should of course be avoided by individuals
11 having any knee prosthesis. Fatigue is not of concern
12 here (segment S4) since the expected frequency of occur-
13 rence of these stresses is low. Obviously, a patient
14 with such knees should be discouraged from performing deep
15 knee bends or similar exercises. It should be noted
16 that few knee prostheses allow flexion in excess of 90
17 degrees, and those that do, while still allowing reasonable
18 axial rotation, experience far greater contact stress
19 than the present invention. The last region is provided
20 to allow the extreme flexion range which is often needed
21 during sitting, where small loads on the knee are ex-
22 perienced, without producing excessive posterior shift
23 of the intermediate tibial bearing components 117.

24 The two incongruent or line contact phases of contact
25 associated with segments S3 and S4 are tolerated in order
26 to obtain nearly normal flexion and extension motion
27 by providing a reasonable approximation to normal
28 condylar geometry. Incongruency in these phases occurs
29 only in one dimension rather than two dimensions as in
30 most prior art prostheses. Thus, normal knee motion is
31 provided without excessive shift of intermediate tibial
32 bearing components 117 while keeping contact stress
33 within acceptable limits of most normal activity.

34 The second bearing surface 142, FIGURES 18, 19, 20,
35 and 21, is on the inferior side of the intermediate tibial
36 bearing component 117. This bearing surface is composed

29

1 of a flat surface 143 and a projecting dovetail surface
2 144. The flat and dovetail bearing surfaces engage the
3 superior surface 145 of the tibial platform component
4 116 shown in FIGURES 15, 16, 17, and 34, and the track
5 surfaces 146 and 154 therein in area contact.

6 This tibial platform 116, as shown in FIGURES 15,
7 16, and 17, consists of a thick plate 147 with a notched
8 area into which fits the section of the proximal tibia to
9 which the cruciate ligaments are attached. Two curved
10 tracks 148 and 153 are provided in thick plate 147.
11 These curved tracks 148 and 153 receive and partially
12 constrain the two identical intermediate tibial bearing
13 components 117, which can be seen in FIGURES 32A and 32B. These
14 bearing inserts are substantially identical to the intermediate tibial
15 bearing component illustrated in FIGURES 18 thru 21.

16 The shape of the thick plate 147 of the tibial plat-
17 form component 116 is contoured so as to engage, where
18 practical, the outer cortical bone of the tibia so as to
19 improve load bearing and to allow this component to be
20 used for both right and left tibias. Three short spikes
21 149, 149, and 172 help distribute joint loads, supply
22 additional load transfer to the cancellous bone, and
23 provide resistance against possible tensile loading.

24 It will be understood that the symmetry of both
25 intermediate tibial bearing component 117 and tibial
26 platform component 116 eliminates the need to designate
27 a right or left knee aspect, and thus eliminates the
28 concern of the implanting surgeon with these matters
29 during implantation.

30 In FIGURE 16, it can be seen from the shape of
31 curved tracks 148 that as the intermediate tibial bearing
32 components 117 move forward and rearward from the central
33 position that they move somewhat closer together, as
34 shown in FIGURES 35A, 35B, and 36. It may be seen from FIGURES 37A and
35 37B that the use of an eccentric bearing insert allows
36 a relatively great inward shift with little incongruency.

35 1 For example, a total movement of ± 6 mm produces a separation change of 0.5 mm. This change of separation is
2 easily accommodated by using a very slightly incongruent
3 surface and/or by providing a slight clearance between
4 the walls 150 and 151 (FIGURE 34) of curved tracks 148,
5 and the mating projecting dovetail surfaces 144 of the
6 intermediate tibial bearing component 117, shown in
7 FIGURE 19. The contact congruency ratio C, when contact
8 is made with segment S2 of the femoral prosthesis, used
9 in one embodiment is approximately 0.99, where C is
10 defined as follows: *PS* *PS*

11 *TI 32,40* $C = R_2/R_2'$ *PS*

12 where

13 *Pi 32* R_2 = Spherical radius of primary load bearing
14 segment S2 of bearing surface 121 on
15 femoral component 111 (FIGURES 7,8);

16 and

17 *Pi 32* R_2' = Spherical radius of primary load bearing
18 surface 141 of the intermediate tibial
19 bearing component 117 (FIGURES 19,20).

20 *P* The contact stress is thus kept quite low while
21 still allowing the needed change in separation.

22 In addition to the anterior-posterior shift, axial
23 rotation of the tibia takes place during flexion. This
24 rotation is accommodated by the shape of the contacting
25 surfaces, and in particular by the spherical radii of the
26 primary load bearing segment S2 of the femoral component
27 111 and primary load bearing surface 141 of intermediate
28 tibial bearing component 117, as well as by the curvature
29 of the curved tracks 148 and 153 of tibial platform
30 component 116. As can best be seen from FIGURE 16, the
31 center 152 of curvature of the left curved track 153 of
32 tibial platform 116 is on a line normal to left track
33 surface 154. This line, on which lies the center 152 of
34 curvature of the left curved track 153, passes through the
35 center 155 (refer to FIGURE 7) of the right spherical
36 center 155 (refer to FIGURE 7) of the right spherical

1 radius of the primary load bearing segment S2 of femoral
2 component 111 when the components are all assembled.
3 Thus, if one were to hold the prosthesis so that it could
4 only rotate about this normal line, the motion could
5 be accommodated (even with perfect congruency and rigidity
6 of the plastic) by virtue of the spherical contact on
7 the right side and the track curvature on the left.
8 Similarly, motion about a normal on the left side could
9 also be accommodated. Axial motion about any other
10 normal axis expected in the knee produces slight inward
11 motion of the intermediate tibial bearing components 117
12 as shown in FIGURE 36. This inward motion, as in the
13 case where this motion is produced by anterior-posterior
14 shift, is accommodated with the very slight incongruency
15 used, and/or the slight clearance provided between the
16 projecting dovetail surfaces 144 of intermediate tibial
17 bearing components 117 and curved tracks 148 and 153 of
18 tibial platform component 116.

19 The less constrained prior art Oxford knee also
20 provides for axial rotation and anterior-posterior shift
21 even with perfect congruency. In the present invention,
22 such motion is obtained while allowing the utilization of
23 stabilizing tracks.

24 The method of track engagement utilized in the
25 present invention has several functions:

26 1. It prevents rotation of the intermediate tibial
27 bearing components 117, and thus:

28 (a) Allows a noncircular and larger bearing
29 insert, ~~platform~~ ^{form in plan view} 156 (in FIGURE 38A), as
30 compared with the smaller, ~~platform~~ ^{form in plan view} 157 of the prior art Oxford insert. The present
31 invention also produces a greater dislocation
32 height 158 as compared with the dislocation
33 height 159 of the prior art Oxford insert as
34 shown in FIGURE 38B. This added height also
35 allows large shifting forces for moving the
36

1 bearing insert anteriorly and posteriorly
2 against the friction generated by the
3 large compressive load.

4 (b) Allows use of a noncentral (i.e. noncentral
5 when viewed in the anterior-posterior direction)
6 spherical radius 160, as can be seen from
7 FIGURE 38C, providing additional medial or
8 lateral stability by virtue of the relatively
9 large inside engagement height 161. This is
10 to be contrasted with the central spherical
11 radius 162 of the prior-art Oxford knee, with
12 its resultant relatively small inside engage-
13 ment height 163. The improved engagement
14 of the present invention is unaffected by axial
15 rotation or anterior-posterior shift. Such is
16 not the case in conventional designs.

17 2. It provides a partially self-retaining feature
18 for the curved tracks 148, 153. This feature, plus the
19 longer intermediate tibial bearing components 117,
20 eliminates the possibility of tipping and dislocation
21 associated with the prior art prostheses ~~discussed earlier~~
22 discussed earlier.

23 3. The curved tracks 148, 153 provide thrust surfaces
24 allowing most medial-lateral shear loads to be taken
25 entirely by the prosthesis with no prosthesis-bone
26 rubbing contact as in the Oxford knee.

27 Thus the present invention, the New Jersey Meniscal
28 Insert Knee Replacement (NJMIK) sacrifices a small
29 amount of congruency (and simplicity) to achieve greatly
30 improved stability. The advantages and differences of
31 the NJMIK compared to the prior-art Oxford knee design
32 can be summarized as follows:

33 1. Use of smaller major generating radii for the
34 posterior segments S3 and S4 (FIGURE 8) of femoral
35 component 111, thus allowing full flexion and allowing
36 such flexion without excessive shift of the intermediate

- 1 tibial bearing components 117;
- 2 P 2. Elimination of possible intermediate tibial bear-
- 3 ing component dislocation modes;
- 4 P 3. Provision of greater insert shifting forces to
- 5 overcome friction;
- 6 P 4. Provision of greater medial-lateral stability;
- 7 and,
- 8 P 5. Provision of effective patello-femoral articul-
- 9 ation coupled with tibio-femoral articulation.

10 The primary disadvantage of the NJMIK, which also is
11 present in the human knee, is the loss of excellent bear-
20 12 ing congruency beyond about 40° flexion, as previously
13 described. It therefore seems a very advantageous trade-
14 off considering the limitations inherent in the prior-
15 art Oxford knee design.

16 Additional benefits result from the tibial fixation
17 methods employed.

18 Loosening and collapse of the tibial component are
19 major problems in knee replacement. This is true of the
20 MacIntosh type onlays used in the prior-art Oxford knee.
21 The problems with this type of platform are depicted in
22 FIGURE 39A, which shows posterior load 164 and lateral
23 load 165. Note that posterior load 164 produces high
24 compressive stress at the posterior aspect of the tibia,
25 with tensile stress at the anterior aspect. The anterior
26 portion of the tibial onlay tends to lift as a result
27 of the tensile stress, as can be seen from FIGURE 39A.
28 There is also a large stress concentration effect of the
29 fixation fin 166. The tipping of the tibial onlay also
30 produces large posterior or lateral compressive bone
31 stress, thereby increasing the tendency toward bone
32 collapse as shown in FIGURE 39B.

33 In the unicompartmental version of the present
34 invention, tibial platform 167 of FIGURES 40A and 40B for example,
35 tipping loads are resisted by reactive compressive loads
36 on the spike 168. Spike 168 also helps support the

1 direct compressive loads as well, as can be seen from FIGURES
2 41A and 41B. In FIGURES 41A and 41B, posterior load 164
3 and lateral load 165 are shown similarly to FIGURES 39A and 39B.
4 The combined effects (tipping loads resisted by reactive
5 compressive loads on spike 168, and direct compressive
6 loads partially supported by spike 168) result in relative-
7 ly low contact stresses on the bond, in the case of the
8 tibial platform 167 according to the present invention.

9 The tibial platform component 116 according to the
10 present invention resists tipping forces by means of a
11 bridge 169, which can be seen in FIGURE 16. Bridge 169
12 connects the two tibial plateau sections 170 and 171,
13 and transfers some of the load from one plateau section
14 to the other, as can be seen from FIGURE 42A. Shown
15 for comparison in FIGURE 42B is a prior-art prosthesis
16 with a flexible platform, which is ineffective in produc-
17 ing any load-sharing across the prosthesis-bone inter-
18 face. Also, the short anterior spike 172 of the present
19 invention, shown in FIGURES 15 and 17, serves to resist
20 posterior loads. Furthermore, bridge 169 inhibits the
21 outward splaying fracture of the tibial condyles depicted
22 in FIGURE 39B.

23 It will be further understood by those skilled in
24 the art and referring again to the femoral component 111
25 and the patella prosthesis 112, that the bearing surfaces
26 173 and 138 of the patella fixturing component 114
27 (FIGURE 13) and bearing surfaces 137 and 134 of the
28 intermediate patella component 113 (FIGURE 10) accommodate
29 both axial surgical misalignment and normal rotation while
30 permitting area contact between the bearing segments S1
31 and S2 of the femoral component 111 and the load-bearing
32 surface 125 of the intermediate patella bearing component
33 113. Similarly, it will be further understood that the
34 bearing surfaces 143 and 144, respectively, of the
35 intermediate bearing components 117 (FIGURES 18-21) and
36 the mating bearing surfaces of the tibial platform

1 component 116 accommodate both axial surgical misalign-
2 ment and normal rotation while permitting sliding sub-
3 stantial ~~area~~ area contact between the primary load bearing
4 segment S2 of femoral component 111 and the primary
5 load bearing surface 141 of the intermediate tibial
6 bearing component 117. This substantial congruence is
7 provided in the important stance phase of walking illust-
8 rated diagrammatically in FIGURE 29A.

9 Referring now to FIGURES 43-46, there is shown a
10 bicompartimental embodiment of the present invention
11 which utilizes a pair of individual femoral components
12 174 and 175 and, as illustrated diagrammatically in
13 FIGURES 45 and 46, omits the use of the patella pros-
14 thesis 112. Referring specifically to FIGURES 43 and 44,
15 there is shown a right individual femoral component
16 174 and it will be understood that the individual
17 femoral component 175 shown in FIGURES 45 and 46 is the
18 mirror image of the right femoral component 174 shown in
19 FIGURES 43 and 44. Tibial prosthesis 115 of this embodi-
20 ment is the same as the tibial prosthesis 115 already
21 described. It will be understood, and referring to
22 FIGURE 46, that the individual femoral components, e.g.
23 175, are provided with a load bearing surface 176
24 which is identical to the segments S4, S3, and a major
25 portion of the primary load bearing segment S2 shown in
26 FIGURE 8. Thus, it will be further understood that
27 segment S2 of these individual femoral components 174
28 and 175 are in area contact with the primary load
29 bearing surface 141 of the intermediate tibial bearing
30 component 117 as taught above, thus providing the same
31 tibio-femoral articulation as described above. For
32 unicompartmental replacement a tibial platform 177, as
33 shown in FIGURES 47A and 47B, is used together with an intermed-
34 iate tibial bearing component 117, as shown in FIGURES
35 18-21. FIGURES 47A and 47B show the assembly of tibial platform
36 177 and intermediate tibial bearing component 117 to

1 form a unicompartmental knee replacement.

2 Referring again to FIGURES 18-21, it will be still
3 further understood by those skilled in the art that
4 the intermediate tibial bearing component 117 may be
5 easily removed intraoperatively to allow replacement of
6 this component with an intermediate tibial bearing comp-
7 onent having a thickness providing proper ligamentous
8 (collateral ligaments) tension.

9 Thus, a number of intermediate tibial bearing
10 components of varying thicknesses may be provided so that
11 the implanting surgeon may shim for proper ligamentous
12 tension or for valgus angle without disturbing fixtured
13 components, e.g. tibial platform component 116 and
14 femoral component 111. Further, such structure allows
15 easy replacement of the intermediate tibial bearing
16 component 117 in the event of unusual or unexpected
17 wear or deformation. Similarly, this is true with
18 respect to the patella prosthesis 112 wherein the inter-
19 mediate patella bearing component 113 may be of varying
20 thicknesses and replaceable in the event of unusual or
21 unexpected wear or deformation.

22 It will be further understood that the femoral
23 component 111, the patella fixturing component 114, and
24 the tibial platform component 116 may be made prefer-
25 ably of a surgical metal such as cobalt-chromium alloy or
26 titanium or stainless steel but may be made of any
27 relatively rigid material (compared with the grouting
28 agent) that is biocompatible, capable of withstanding
29 the applied loads, and possesses adequate bearing prop-
30 erties against the intermediate bearing inserts, e.g. the
31 intermediate patella bearing component 113 and inter-
32 mediate tibial bearing component 117 may be made of any
33 biocompatible material strong enough to withstand loads
34 and adequate in bearing against the material with which
35 it is engaged. Preferably these components are made of
36 a plastic, such as ultra-high molecular weight poly-

1 ethylene or copolymer acetal.

2 A prosthetic ankle, an alternate embodiment of the
3 present invention, is shown in FIGURES 48, 49, and 50.
4 Talar platform component 178 is implanted in the talus,
5 and tibial component 179 is implanted in the distal
6 tibia. Intermediate bearing component 180 is interposed
7 between talar platform component 178 and tibial component
8 179. Talar platform component 178 has a superior bearing
9 surface 181, seen in FIGURE 48, which consists of a
10 segment of a surface of revolution produced by a generat-
11 ing curve, as can be seen in FIGURES 48 and 50. The
12 generating curve, in this case, may typically consist
13 of two 0.625 inch radius circular arcs connected by two
14 20° tangent lines to a 0.250 inch radius circular arc.
15 This arrangement is similar in form to the generating
16 curve used for the knee embodiment previously described.

17 The inferior portion of talar platform component 178
18 includes a fixation fin 182, seen in FIGURE 48, with serr-
19 ated sides for implantation into the talus. Tibial comp-
20 onent 179 consists of a flat plate 183 with serrated
21 top edge 184 and a fixation fin 185, both of which are
22 used for implantation into the tibia. The plastic inter-
23 mediate bearing component 180 has an inferior bearing
24 surface 186 complementary to the superior bearing surface
25 181 of talar platform component 178. Intermediate bear-
26 ing component 180 is also provided with a flat superior
27 bearing surface 187 which matches flat inferior bearing
28 surface 188 of tibial component 179.

29 It is important to recognize that the superior
30 bearing surface 181 of talar platform component 178,
31 by virtue of its shape, acts as a track to constrain
32 the motion of intermediate bearing component 180.

33 The ankle prosthesis illustrated in FIGURES 48-50
34 provides flexion-extension motion by rotation of the talar
35 platform component 178 relative to the intermediate
36 bearing component 180. There is sliding engagement of

1 the inferior bearing surface 186 of intermediate bearing
2 component 180 with the superior bearing surface 181 of
3 talar platform component 178 as the ankle is flexed or
4 extended, thereby providing flexion-extension motion
5 between the tibia and the talus.

6 Sliding engagement of the flat superior bearing
7 surface 187 of intermediate bearing component 180 with
8 the flat inferior bearing surface 188 of tibial component
9 179 allows anterior-posterior translation as well as
10 limited medial-lateral translation. The medial-lateral
11 translation is constrained by anatomical features,
12 namely the maleoli of the ankle. The anterior-posterior
13 motion is constrained by the action of the ligaments.
14 Thus, the prosthesis of FIGURES 48-50 includes no
15 mechanical constraints against anterior-posterior or
16 medial-lateral translation, a desirable feature because
17 it minimizes force loads on the components of the pros-
18 thesis.

19 The prosthetic joint of FIGURES 48-50 also allows
20 axial rotation, that is, rotation about the axis of the
21 femur, without any restraint other than that provided
22 by natural tissues. In addition, it provides unrestrain-
23 ed flexion-extension. The purpose of the track (i.e.
24 the characteristic shape of the generating curve used
25 for the superior bearing surface 181 of talar platform
26 component 178) is to retain the intermediate bearing
27 component so as to prevent its moving outside the medial-
28 lateral borders of talar platform component 178. In
29 this way intermediate bearing component 180 is prevented
30 from impinging upon adjacent bone.

31 The prosthetic joint of FIGURES 48-50 differs from
32 one-half of the prior-art Oxford knee by virtue of the
33 track-type of contact between talar platform component 178
34 and intermediate bearing component 180, and also because
35 it affords flexion-extension motion without the possibil-
36 ity of eversion-inversion, at least so long as the joint

1 is under compressive force loads (the normal situation).
2 Axial rotation only is provided by the sliding engagement
3 of the flat superior bearing surface 187 of intermediate
4 bearing component 180 with the flat inferior bearing
5 surface 188 of tibial component 179. The prior-art
6 Oxford knee, on the other hand, incorporates a spherical
7 bearing arrangement allowing three degrees of freedom of
8 rotational motion, rather than two, as provided by the
9 ankle prosthesis according to the present invention.

10 An implanted prosthetic ankle is shown in
11 FIGURES 51 and 52. Visible in FIGURES 51 and 52 are
12 talar platform component 178, intermediate bearing compo-
13 nent 180, and tibial component 179. For comparison, an
14 anatomical ankle is illustrated in FIGURES 53 and 54.

15 It will be recognized that the track of the present
16 invention, which serves to constrain motion of a bearing
17 insert, can take many forms. For example, there is the
18 track with retention, shown in cross-section in FIGURE 34,
19 and there is the track of the ankle prosthesis of
20 FIGURE 48. FIGURE 55 illustrates, in cross-section,
21 still another type of track, suitable for applications
22 where force loads applied to the prosthetic joint are
23 such as to insure retention of bearing insert 189
24 against shoulder 190 of platform component 191.

34

35

36

a

1 SURGICAL IMPLANTATION PROCEDURE FOR KNEE ENDOPROSTHESIS

2 **P** The patient is placed in a supine position on the
3 operating table. The knee is prepped and draped in a
4 sterile fashion. A thigh tourniquet previously applied
5 is inflated to 400mm Hg after elevation of the leg for
6 one minute to allow for venous run-off.

7 The knee is fully extended and a gently curved
8 S-shaped incision is made on the tibial tubercle up
9 towards the medial border of the patella tendon, then
10 curving posteriorly along the medial border of the
11 vastus medialis.

12 The medial retinaculum, capsule and synovial layer
13 are incised in line with the skin incision. The vastus
14 medialis muscle belly is elevated free from its attach-
15 ment to the adductor magnus tendon. The patella is
16 reflected laterally exposing the entire tibio-femoral
17 joint. If there is excessive tension in the quadriceps
18 mechanism preventing complete lateral displacement of the
19 patella, then sharp detachment of the medial 1/4 of the
20 patella tendon from the tibial tubercle may be necessary.
21 In a similar fashion, further blunt dissection of the medial
22 attachment of the vastus medialis may be needed to mobilize
23 the quadriceps mechanism proximally. These maneuvers
24 will allow complete flexion of the knee to 110 degrees
25 with complete anterior exposure of the joint. **P**

26 At this time, excision of hypertrophic synovium
27 and redundant fat pad is performed. Medial and lateral
28 meniscectomy will facilitate exposure of the tibial plateau
29 borders and should be performed. Examination of the
30 intercondylar contents will reveal the condition of the
31 cruciates. Redundant synovium should be excised from this
32 region to prevent possible impingement or overgrowth
33 onto the tibial component surface

34 With the proximal tibial and distal femur cleared
35 of soft tissue debris, bone guards are slid posteriorly
36 between the collateral ligaments and the posterior

41

182,41 1 capsule to protect the posterior neurovascular bundle
2 during resection of the articular surfaces. A 3/4"
3 periosteal elevator may be used to develop the soft
4 tissue planes for the bone guards, which also serve as
5 knee retractors.

174,41 6 The knee is flexed to 100 degrees and a drill hole
7 at the intercondyler notch border is made with a 1/4" drill.
8 The drill is taken down to the level of the
9 posterior femoral shaft. Next, a tibial resection jig
10 is placed with a spike located on the posterior aspect
11 of the femoral shaft and a distal limb of the instrument
12 parallel to the tibia. With the collateral ligaments
13 in tension during this flexion phase, a proper resection
14 plane is insured by use of the parallel cutting slots
15 available in the jig. The jig has an automatic 10
16 degree retroversion angle insured when the knee is
17 flexed parallel to the distal limb of the jig. Using
18 an oscillating saw, the tibial preparation is made
19 leaving a ridge of bone to which the cruciate ligaments
20 insert. The resection planes are made at 5, 10, or 15mm,
21 depending upon the amount of bone stock available for
22 perpendicular loading of the tibial component. Once
23 the proper flexion tension has been achieved and the bone
24 resection has been made, the tibial alignment jig is
25 removed from the femoral shaft and the femoral shaper is
26 next replaced into the same channel. The femoral shaper
27 is situated such that the anterior and posterior cuts are
28 symmetrically parallel to the femoral condyles. Using
29 again an oscillating saw in these cuts, the anterior
30 surface and posterior condyles of the femur are resected.
31 The knee is then brought into full extension after
32 removal of the femoral shaper and an extension femoral
33 alignment jig is placed into the joint. With manual
34 traction on the femur and aligning an adjustable valgus
35 guide into 5 to 10 degrees of physiologic valgus, the
36 horizontal cut on the distal femur is made to insure

42

1 adequate extension tension of the collateral ligaments.
2 Once this cut has been made using the oscillating saw,
3 the extension alignment jig is removed from the knee joint.
4 The knee is again flexed and an oblique osteotomy jig
5 is replaced into the fixturing hole and using a mallet
6 impacted into the distal femoral bone stock. The
7 anterior and posterior oblique cuts are then made in line
8 with the jig surface and a central notch of the oblique
9 osteotomy jig is used to trim away the boney surface for
10 the anterior femoral flange. The oblique osteotomy jig
11 is removed and the alignment holes made by the jig are
12 curetted out to accept the fixturing pins of the femoral
13 prosthesis. A trial fit of the femoral component is
14 next made. Excessive bone stock is trimmed to insure
15 proper contact of all surfaces. Next, the tibial prepara-
16 tion is completed. A marking template is used to mark
17 out the tibial component spike positions. Following
18 marking with methylene blue, tibial component spike
19 channels are fashioned using a curette or gouge. A trial
20 seating of the tibial component is next made and proper
21 bone resection is performed at this time to insure
22 excellent metal to bone contact of the prosthesis. With
23 resections of both bones now finished, the trial reduction
24 of the tibial and femoral components is made as follows:

25 The metal tibial component is placed on the proximal
26 tibia and the appropriate intermediate bearing components
27 are inserted into place. Next, the femoral component
28 is placed in its proper position and the knee joint is
29 tested in both flexion and extension for proper ligament-
30 ous tension. If resection cuts have been made properly,
31 there should be no gross instability. Should mild laxity
32 exist in flexion and extension, then thicker intermediate
33 tibial bearing components may be used to tighten the
34 collateral ligaments. The bearing heights come in 2.5mm
35 increments and may be used to finely adjust the ligamentous
36 tension at this stage. These may also be used to correct

1 varus-valus alignment. Once the tibial-femoral resect-
2 ions have been properly prepared, attention is given to
3 the patella replacement. Using a scalpel, the synovial
4 tissue and retinaculum are freed from the periphery of
5 the patella down to the level of the patella tendon.
6 A reciprocating saw is then used to remove the articular
7 surface. The plane of the cut should parallel the infer-
8 ior surface of the patella tendon.

9 A patella marking template is now centered over the
10 horizontal and vertical axis of the patella with the long
11 fixturing fin directed toward the lateral aspect.
12 Methylene blue dye is used to mark the fin channels for
13 the fixturing fins of the component. These channels are
14 taken to a depth of 1/4" and undercut for mechanical
15 locking of the cement.

16 The trial patella replacement can now be seated to
17 assess the fit. Any boney impingement is removed to
18 insure proper seating. The patella is reflected to its
19 anatomical position to check the alignment in the femoral
20 track. A range of motion may now be tested with all
21 three components in place. The patella prosthesis should
22 center in the femoral track and easily glide along the
23 femoral flange without binding. Restricting adhesions
24 or boney impingement should be completely corrected at
25 this time.

26 The components are removed after a satisfactory
27 trial fit and the wound is thoroughly irrigated with
28 antibiotic saline solution. The first batch of methyl-
29 methacrylate is mixed and placed on the tibial surface
30 with the knee in the flexed position. The tibial comp-
31 onent is gently slid into its fixturing channels and
32 firmly held in compression until complete polymerization
33 has been obtained. During the setting phase, excess
34 methylmethacrylate may be trimmed using a scalpel and
35 curette from the edges of the tibial component. Next,
36 the bearing components are placed into the tibial component

44

1 and the femoral component is cemented in place. Excess
2 methylmethacrylate is removed from around the femoral
3 component to insure that the bearing surface will remain
4 free of this abrasive agent. With a third batch of
5 methylmethacrylate, or else using a portion of that
6 cement used for the femoral component, the cancellous
7 patella bed is covered. The patellar component fixturing
8 fins are firmly pressed into their mating channels and
9 the component is held tightly with a patellar component
10 clamp. Excess methylmethacrylate may now be removed
11 from the edges of the patella backplate. Upon complete
12 polymerization of all cement beds, a range of motion is
13 again tested after returning the patella to its anatomical
14 position. Two medium sized hemovac drains are now
15 placed in the joint space and brought to exit laterally
16 above the incision line. A single layer closure of
17 capsule and retinaculum is performed with #2-0 chromic
18 suture with the knee flexed 30 degrees for the first
19 several sutures, then to 60 degrees with the second set
20 of sutures, and finally, to 90 degrees for the remaining
190 closure sutures. Subcutaneous tissue is closed with #3-0
21 plain suture, skin is re-approximated in a tension-free
190 fashion with #3-0 nylon suture. Hemovac drains are hooked
22 to suction and a Robert-Jones compression dressing is
23 applied. The leg is elevated and the patient is taken to
24 the recovery room where ice packs are placed about the
25 knee.
